

ABSTRACT

- Nowadays, eHealth service has become a booming area, which refers to computer-based health care and information delivery to improve health service locally, regionally and worldwide.
- An effective disease risk prediction model by analyzing electronic health data benefits not only to care a patient but also to provide services through the corresponding data-driven eHealth systems.
- In this paper, we particularly focus on predicting and analyzing diabetes mellitus, an increasingly prevalent chronic disease that refers to a group of metabolic disorders characterized by a high blood sugar level over a prolonged period of time.
- K-Nearest Neighbor (KNN) is one of the most popular and simplest machine learning techniques to build such a disease risk prediction model utilizing relevant health data.
- In order to achieve our goal, we present an optimal K-Nearest Neighbor (OPT-KNN) learning based prediction model based on patient's habitual attributes in various dimensions.
- This approach determines the optimal number of neighbors with low error rate for providing better prediction outcome in the resultant model.
- The effectiveness of this machine learning eHealth model is examined by conducting experiments on the real-world diabetes mellitus data collected from medical hospitals.

CHAPTER-1

INTRODUCTION

1.1 OVERVIEW

Diabetes may be a set of metabolic problems known by high blood sugar levels over a protracted period of our time. Diabetes is outlined as a bunch of metabolic disorders in the main caused by abnormal insulin secretion and/or action. Symptoms of high aldohexose incorporate excessive voiding, continually feeling thirsty and enlarged hunger. If not treated on time, diabetes will cause serious health problems in a person like diabetic acidosis, hyperosmolar hyperglycemic state, or maybe result in death. This could result in time period complications as well as vas upset, brain stroke, failure, ulcers within the foot, and eye complications etc. Diabetes is caused once the duct gland within the body is unable to come up with insulin in enough amounts or once the cells and tissues within the body fail to utilize the insulin created. Diabetes exists in 3 forms: Diabetes Mellitus Type-1 is characterized by duct gland generating insulin but what's needed by the body, a condition conjointly referred to as "insulin-subordinate diabetes mellitus" (IDDM). Folks littered with type-1 DM need external insulin indefinite quantity to form up for the less insulin created by the duct gland. Diabetes Mellitus Type-2 is marked by the body resisting insulin because the body cells react otherwise to insulin than they traditional would. This could ultimately result in no insulin within the body. This can be otherwise referred to as "non-insulin subordinate diabetes mellitus" (NIDDM) or "adult beginning diabetes". This sort of diabetes is often found in folks with high BMI or people who lead associate degree inactive manner. Gestational diabetes is that the third principle structure that's ascertained throughout physiological state. Generally, for a traditional person, aldohexose levels vary from seventy to ninety-nine milligrams per deciliter. An individual is taken into account diabetic providing the fast aldohexose level is found to be over 126 mg/dL. Within the practice, an individual having an aldohexose concentration of a hundred to one hundred twenty-five mg/dL is taken into account as pre-diabetic. Such an individual is susceptible to the event of sort two diabetes. Over the years, it's been found that folks with the subsequent health characteristics face a larger risk against diabetes:

- A Body Mass Index worth larger than twenty five
- Members of the family littered with diabetes
- People with cholesterol concentration within the body but forty mg/dL prolonged high blood pressure having physiological condition diabetes
- People World Health Organization have suffered from polycystic ovary disorder within the past
- People happiness to ethnic teams like African American, or Native American, or Spanish American, or Asian-pacific aged over forty five years
- Having associate degree inactive manner

1.2 OBJECTIVE

- Diabetes mellitus (DM) is one of the most prevalent chronic non-communicable diseases (NCD) around the world; about 90% of the patients who have diabetes suffer from Type 2 DM (T2DM)
- The risk of developing T2DM is strongly associated with many predispositions, behavioral, and environmental risk factors and also genetic factors

1.3 SCOPE/MOTIVATION

- About 90% of patients who have diabetes suffer from Type 2 DM (T2DM)
- Many studies suggest using the significant role of Incnas to improve the diagnosis of T2DM.
- Machine learning is the techniques are tools that can improve the analysis and interpretation or extraction of knowledge from the data.
- These techniques may enhance the prognosis and diagnosis associated with reducing diseases such as T2DM.

- We applied four classification models, including K-nearest neighbor (KNN)

CHAPTER-2

LITEARTURE SURVEY

2.1 Prediction of Diabetes using Classification Algorithms

Diabetes isn't a hereditary disorder however heterogeneous group of disorder which could ultimately result in an boom of glucose within the blood and lack of glucose inside the urine. Diabetes is typically resulting from genetics, way of life and surroundings. Eating an dangerous weight loss plan, being overweight play role in developing the diabetes. High blood sugar tiers can also result in kidney diseases, coronary heart illnesses. The excess of sugar in the blood can harm the tiny blood vessels in your frame. Signs of diabetes are blurry imaginative and prescient , extreme hunger, unusual weight reduction, common urination and thirsty. In this paper, parameters used within the facts set to locate the diabetes are Glucose, Blood pressure, pores and skin thickness, Insulin, Age. Huge volumes of statistics units are generated by health care industries. Those facts sets is a collection of patient information about the diabetes from the hospitals. Big records analytics is the processing which it examines the information units and exhibits the hidden information. Pima Indians Diabetes Database (PIDD), this dataset is taken from the national Institute of Diabetes and Digestive diseases. The objective of the dataset is to predict whether or not the patient has diabetes or not, primarily based on diagnostic measurements in the dataset. Several constraints were taken from the massive database.

2.2 A Novel Technique To Predict Diabetic Disease Using Data Mining Classification Techniques

Data mining is the process of analyzing data from different perspectives and summarizing it into useful information. The software of data mining is an analytical tool for analyzing data. Data mining has become a main strategy in many industries to improve outputs and decrease costs. Now days in healthcare management this field will become very useful. Data mining techniques has become great potential for the healthcare industry to predict health deceases by using systematic data and analytics to identify inefficiencies and best practices that improve care and reduce costs. These techniques are fast in nature and take less time for the prediction

system to improve the diabetic decease with more accuracy. In this paper we are applying the various classification techniques over diabetic mellitus decease dataset for the prediction of decease and non decease person. The diabetic database is preprocessed to make the mining process more efficient. The preprocessed data is used to predict using classification algorithms like Discriminant analysis, KNN, Naïve Bayes and Support vector machine. These classifiers can be efficiently used in bioinformatics problem. We are analyzing the various classification techniques like Discriminant analysis, KNN, Naïve Bayes and Support vector machine with linear and RBF kernel function and showing their accuracy.

2.3 Review on Prediction of Diabetes using Data Mining Technique

Diabetes mellitus is one of the world's major diseases. Millions of people are affected by the disease. The risk of diabetes is increasing day by day and is found mostly in women than men. The diagnosis of diabetes is a tedious process. So with improvement in science and technology it is made easy to predict the disease. The purpose is to diagnose whether the person is affected by diabetes or not using K Nearest Neighbor classification technique. The diabetes dataset is a taken as the training data and the details of the patient are taken as testing data. The training data are classified by using the KNN classifier and secondly the target data is predicted. KNN algorithm used here would be more efficient for both classification and prediction. The results are analyzed with different values for the parameter k.

2.4 A Prediction Technique in Data Mining for Diabetes Mellitus

Diabetes mellitus is a chronic disease characterized by hyperglycemia. It may cause many complications. According to the growing morbidity in recent years, in 2040, the world's diabetic patients will reach 642 million, which means that one of the ten adults in the future is suffering from diabetes. There is no doubt that this alarming figure needs great attention. With the rapid development of machine learning, machine learning has been applied to many aspects of medical health. In this study, we used decision tree, random forest and neural network to predict diabetes mellitus. The dataset is the hospital physical examination data in
